### In past few years ESE Main exam has evolved as an examination designed to evaluate a candidate's subject knowledge. Studying engineering is one aspect but studying to crack prestigious ESE exam requires altogether different strategy, crystal clear concepts and rigorous practice of previous years' questions. ESE mains being conventional exam has subjective nature of questions, where an aspirant has to write elaborately - step by step with proper and well labeled diagrams and figures. This characteristic of the main exam gave me the aim and purpose to write this book. This book is an effort to cater all the difficulties being faced by students during their preparation right from conceptual clarity to answer writing approach.

MADE EASY Team has put sincere efforts in solving and preparing accurate and detailed explanation for all the previous years' questions in a coherent manner. Due emphasis is made to illustrate the ideal method and procedure of writing subjective answers. All the previous years' questions are segregated subject wise and further they have been categorised topic-wise for easy learning and helping aspirants to solve all previous years' questions of particular area at one place. This feature of the book will also help aspirants to develop understanding of important and frequently asked areas in the exam.

I would like to acknowledge the efforts of entire MADE EASY team who worked hard to solve previous years' questions with accuracy. I hope this book will stand upto the expectations of aspirants and my desire to serve the student community by providing best study material will get accomplished.

# Analog and Digital Communication Systems

**Revised Syllabus of ESE:** Random signals, noise, probability theory, information theory; Analog versus digital communication & applications: Systems- AM, FM, transmitters/receivers, theory/practice/ standards, SNR comparison; Digital communication basics: Sampling, quantizing, coding, PCM, DPCM, multiplexing-audio/ video; Digital modulation: ASK, FSK, PSK; Multiple access: TDMA, FDMA, CDMA.

#### 1. Analog Communication Systems

- 1.1 (i) In FM radio broadcasting, the modulation index is 40%. What is the value of frequency deviation?
  - (ii) In an FM modulation system, the modulation index is doubled. By what percentage does the total transmitted power increase?
  - (iii) For the following microwave coaxial connectors write the full form and the frequency upto which these can be used satisfactorily.
    - 1. APC 3.5 2. BNC 3. TNC 4. SMC

[2 + 2 + 4 marks : 1999]

#### Solution:

- (i) Frequency deviation,  $\delta = m_f f_m$ where  $m_f \rightarrow \text{modulation index}$   $f_m \rightarrow \text{modulating frequency}$ So,  $\delta = 0.4 f_m$
- (ii) In FM, the total transmitted power remains constant. So on doubling the modulation index, there will be 0% change in the total transmitted power. Because in FM, we are concerned about the frequency not on the amplitude.

(iii)	Microwave coaxial connectors	Full form	Maximum Frequency
	APC 3.5	Amphenol Precision Connector - 3.5 mm	34 GHz
	BNC	Bayonet Navy Connector	4 GHz
	TNC	Threaded Navy Connector	1 GHz
	SMC	Sub-miniature Connector	7 GHz

- **1.2** A measuring system is used to calibrate the setting on a CW signal generator. Two adjacent nulls are found on the coaxial slotted line. The scale readings are 12.4 cm and 25.7 cm.
  - (i) What is the wavelength and frequency of the signal generator at this setting?
  - (ii) What cutoff frequency should be selected for the low pass filter?
  - (iii) What must the local oscillator frequency be if the IF amplifier frequency is 60 MHz?
  - (iv) What attenuator should be selected to reduce the reflected power by 12 dB?

Solution:

(i)	$\frac{\lambda}{2}$ = distance between two adjacent nulls
$\Rightarrow$	$\frac{\lambda}{2} = (25.7 - 12.4) = 13.3$
$\Rightarrow$	$\lambda = 2 \times 13.3 = 26.6 \text{ cm}$ Ans.
Frequency	$f = \frac{c}{\lambda}$
$\Rightarrow$	$f = \frac{3 \times 10^{10}}{26.6} = 1.1278 \times 10^9 \text{Hz} = 1.1278 \text{GHz}$

(ii) Cutoff frequency of the LPF,

$$f_c = 1.1278 \,\text{GHz}$$
 **Ans.**

(iii) 
$$f_{L0} = f_c + f_{IF} = 1.1278 \times 10^9 + 60 \times 10^6$$
$$f_{L0} = (1.1278 + 0.06) \times 10^9 = 1.1878 \text{ GHz} \text{ Ans.}$$

(iv) A resistive circuit whose relation is as  $10\log \frac{P_i}{P_o} = 12$  is used as attenuator.

- **1.3** A 10 MHz carrier is frequency modulated using a modulating signal  $e_m = E_m \sin 10^3 \pi t$ . The resultant FM signal has frequency deviation of 5 kHz.
  - (i) Calculate the modulation index of the FM wave.
  - (ii) What should be the capture range of a PLL used for demodulation of this signal?
  - (iii) Derive the result of part (b).

[3 + 6 + 6 marks : 2001]

Conventional

Solved Papers

#### Solution:

(i) Modulation index,  $m_f = \frac{\Delta f}{f_m}$ 

where,  $\Delta f \rightarrow$  frequency deviation and  $f_m \rightarrow$  maximum frequency component of modulating signal.

$$m_f = \frac{5 \times 10^3}{10^3 \pi / 2\pi} = \frac{2 \times 5 \times 10^3}{10^3} = 10$$
 Ans.

(ii)

*.*..

$$f_1 = \frac{10^3}{2} = 500$$
Hz

 $\Delta f = 5 \text{ kHz} = 5 \times 10^3 \text{ Hz}$ 

Input frequency

Capture range (total) 
$$\cong 2\sqrt{f_1\Delta f}$$

$$\stackrel{\cong}{=} 2\sqrt{500 \times 5000}$$
  
= 3.162 × 10<sup>3</sup> Hz = 3.162 kHz

(iii) When PLL is not initially locked to the signal, the frequency of the VCO will be free running frequency  $f_0$ . The phase angle difference between the signal and the VCO output voltage will be

$$\phi = (\omega_{s} \cdot t + \theta_{s}) - (\omega_{o} \cdot t + \theta_{o}) = (\omega_{s} - \omega_{o})t + \Delta\theta$$

thus the phase angle difference does not remain constant but will change with time at a rate given by

$$\frac{d\Phi}{dt} = \omega_s - \omega_0$$

The phase detector output voltage will therefore not have a dc component but will produce an ac voltage with a triangular waveform of peak amplitude  $K_{\phi}(\pi/2)$  and a fundamental frequency  $(f_s - f_o) = \Delta f$ The low pass filter (LPF) is a simple RC network having transfer function

$$T(jf) = \frac{1}{\left(1 + \frac{jf}{f_1}\right)}$$

where  $f_1 = \frac{1}{2\pi RC}$  is the 3-dB point of LPF. In the slope portion of LPF where  $\left(\frac{f}{f_1}\right)^2 >> 1$  then

$$T(f) \cong \frac{f_1}{jf}$$

The fundamental frequency term supplied to the LPF by the phase detector will be the difference frequency  $\Delta f = f_s - f_o$ . If  $\Delta f > 3f_1$ , the LPF transfer function will be approximately

$$T(\Delta f) \simeq rac{f_1}{\Delta f} = rac{f_1}{\left(f_s - f_o\right)}$$

The voltage  $V_c$  to drive the VCO is

or

$$V_{c} = V_{e} \times T(f) \times A$$

$$V_{c \max} = V_{e \max} \times T(f) \times A$$

$$V_{c \max} = \pm K_{\phi} \left(\frac{\pi}{2}\right) A \left(\frac{f_{1}}{\Delta f}\right)$$

$$(\because V_{e \max} = \pm K_{\phi} \left(\pi/2\right))$$

Then corresponding value of maximum phase shift is

$$(f - f_o)_{\max} = K_v V_{c \max} = \pm K_v K_{\phi} \left(\frac{\pi}{2}\right) A \left(\frac{f_1}{\Delta f}\right)$$

For the acquisition of signal frequency, we should put  $f = f_s$ , so that maximum signal frequency range that can be required by PLL is

$$(f_s - f_o)_{\max} = K_v K_{\phi} \left(\frac{\pi}{2}\right) A \left(\frac{f_1}{\Delta f_c}\right)$$

 $\Delta f_c = (f_s - f_o)_{\text{max}}$ 

Now

So 
$$(\Delta f_c)^2 = K_v K_{\phi} \frac{\pi}{2} A f_1$$

But

...

$$\Delta f_{c} = \sqrt{f_{1}\Delta f_{L}}$$

 $K_{\star}K_{\star}\frac{\pi}{A}A = \Lambda f_{\star}$ 

Therefore total capture range

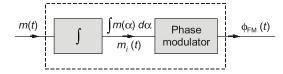

$$\Delta f_{_C} = 2\sqrt{f_1 \,\Delta f_L}$$

**1.4** Explain how frequency modulation may be obtained from a phase modulator. Diagrammatically compare the amplitude modulation, frequency modulation and phase modulation in respect of change in amplitude, frequency and phase when the carrier is modulated with a step function.

[8 marks : 2004]

#### Solution:

Frequency modulation from a phase modulator:

The waveform  $m_i(t)$  is derived as the integral of the modulating signal m(t), i.e.,

$$m_i(t) = k' \int_{-\infty}^t m(\alpha) d\alpha$$

where k' is sensitivity of phase modulator.

Output of phase modulator is

$$v(t) = A\cos[\omega_{c}t + k'' m_{i}(t)]$$

where k'' is sensitivity of phase modulator

$$v(t) = A\cos\left[\omega_{c}t + k\int_{-\infty}^{t}m(\alpha)d\alpha\right]$$

where k = k'k''

The instantaneous angular frequency is

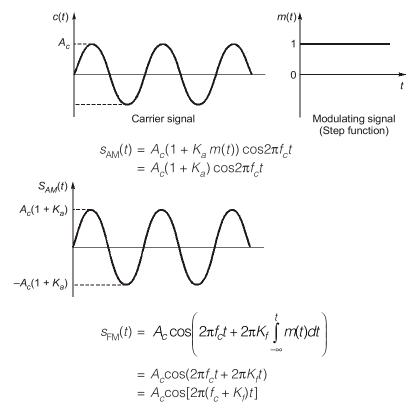

$$\omega_i = \frac{d}{dt} \left[ \omega_c t + k \int_{-\infty}^t m(\alpha) d\alpha \right] = \omega_c + km(t)$$

The deviation of the instantaneous frequency from the carrier frequency  $\omega_c/2\pi$  is

$$\Delta f = f_i - f_c = \frac{k}{2\pi}m(t)$$

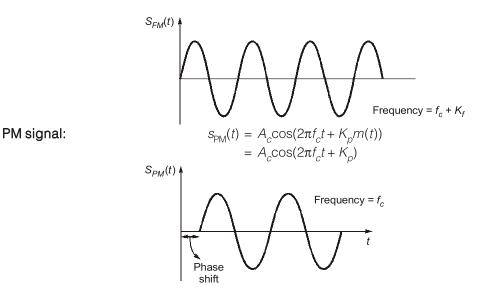

Since the deviation of the instantaneous frequency is directly proportional to the modulating signal, the combination of integrator and phase modulator of the above figure constitutes a device for frequency modulation.

#### Diagrammatically comparison of AM, FM & PM:

FM signal:

AM signal:

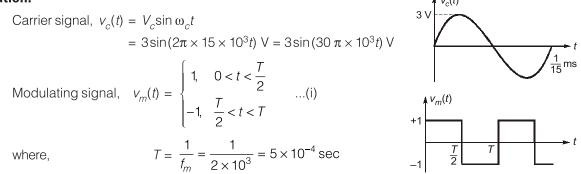

1.5 In a radio broadcast transmitter, the carrier signal is sinusoidal with amplitude of 3 volt and frequency of 15 kHz. The carrier signal is modulated by a square wave that does not have any dc component, yet does have peak-to-peak amplitude of 2.0 volt and frequency of 2 kHz. Write down the mathematical expressions of the carrier signal, the modulating signal and the modulated signal. Neatly plot those waveforms as a function of time. Obtain the plots in frequency domain as well.

#### Solution:

*.*..

[10 marks : 2004]

 $v_m(t)$  is an odd signal with half wave symmetry. So, its trigonometric Fourier series representation has only  $b_n$ terms for odd values of n.

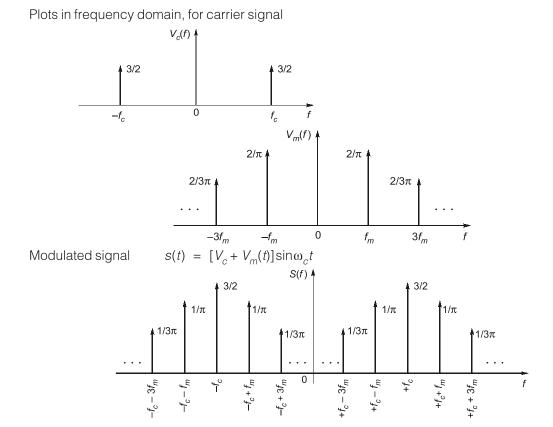

$$a_{0} = a_{n} = 0$$

$$b_{n} = \frac{2}{T} \int_{0}^{T} v_{m}(t) \sin(n\omega_{m}t) dt = \frac{2}{T} \left[ \int_{0}^{T/2} \sin(n\omega_{m}t) dt - \int_{T/2}^{T} \sin(n\omega_{m}t) dt \right]$$

$$= 2 \left[ \frac{1 - \cos(n\pi)}{n\pi} \right]; n = 1, 2, 3 \dots$$
So, modulating signal,
$$V_{m}(t) = \frac{4}{\pi} \sin 2\pi f_{m}t + \frac{4}{3\pi} \sin 6\pi f_{m}t + \frac{4}{5\pi} \sin 10\pi f_{m}t + \dots$$
Modulated signal,
$$s(t) = (v_{c} + v_{m}) \sin \omega_{c}t$$
where,
$$v_{m}(t) \text{ as defined (i)}$$

$$\therefore \qquad s(t) = [v_{c} + v_{m}(t)] \sin \omega_{c}t$$

5

1.6 A 50 MHz carrier delivers 100 W power to a load. The carrier is now frequency modulated by a 1 kHz modulating signal causing a maximum frequency deviation of 6 kHz. This frequency modulated signal is now coupled to the load through an ideal band-pass filter with 50 MHz center frequency and a variable bandwidth. Calculate the power delivered to the load when the filter bandwidth is (b) 2.1 kHz (c) 12.5 kHz (d) 14.5 kHz (e) 20.2 kHz (a) 1 kHz Comment on the result. Given:

$$J_0(6) = 0.1506 ; J_1(6) = -0.2767 ; J_2(6) = -0.2429 ; J_3(6) = 0.1148 ; J_4(6) = 0.3576 ; J_5(6) = 0.3621$$
  
 
$$J_6(6) = 0.2458 ; J_7(6) = 0.1296 ; J_8(6) = 0.0565 ; J_9(6) = 0.0212 ; J_{10}(6) = 0.0060$$
  
 [15 marks : 2008]

#### Solution:

Given that: Carrier frequency, 
$$f_c = 50$$
 MHz,  $f_m = 1$  kHz,  $\Delta f = 6$  kHz and  $P_c = 100$  W

We know that, Modulation index ( $\beta$ ) =  $\frac{\Delta f}{f_m} = \frac{6 \times 10^3}{1 \times 10^3} = 6$ 

Equation of FM, 
$$x_{FM}(t) = A_C \sum_{k=-\infty}^{\infty} J_k(\beta)$$

$$x_{\text{FM}}(t) = A_C \sum_{k=-\infty} J_k(\beta) \cos\{(\omega_c + k\omega_m)t\}$$
  
power P = 
$$\sum_{k=-\infty}^{\infty} \frac{A_c^2}{2} \cdot J_k^2(\beta) = \sum_{k=-\infty}^{\infty} P_C \cdot J_k^2(\beta)$$

For

So,

For 
$$k = 0$$
  
Frequency component  $= f_c \pm 0 = f_c$   
 $P_0 = P_c \times J_0^2(\beta) = 100 \times (0.1506)^2 = 2.268$  Watt  
For  $k = 1$  and  $-1$   
Frequency component  $= f_c \pm f_m = 1$  MHz  $\pm 1$  kHz

 $P_{\mu} = P_{\alpha} J_{\mu}^2(\beta)$ 

Also,

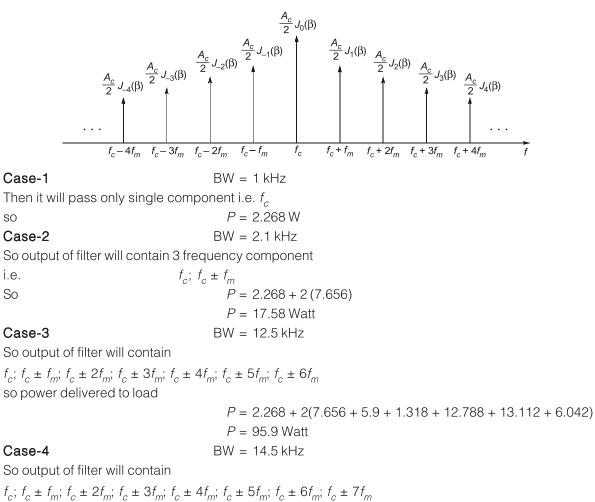

$$J_{-n}(\beta) = (-1)^n J_n(\beta) \text{ i.e. } J_{-1}(\beta) = J_1(\beta)$$
  

$$P_1 = P_c \times J_1^2(\beta) = 100 \times (-0.2767)^2 = 7.656 \text{ Watt}$$

Similarly we can find out the power of other frequency component.

k	Frequency component ( $f_c \pm k f_m$ )	Power (W)
0	50 MHz	2.268
±1	$50 \text{ MHz} \pm 1 \text{ kHz}$	7.656
±2	$50 \text{ MHz} \pm 2 \text{ kHz}$	5.900
±3	$50 \text{ MHz} \pm 3 \text{ kHz}$	1.318
±4	$50 \text{ MHz} \pm 4 \text{ kHz}$	12.788
±5	$50 \text{ MHz} \pm 5 \text{ kHz}$	13.112
±6	$50 \text{ MHz} \pm 6 \text{ kHz}$	6.042
±7	$50 \text{ MHz} \pm 7 \text{ kHz}$	1.679
±8	50 MHz ± 8 kHz	0.319
±9	$50 \text{ MHz} \pm 9 \text{ kHz}$	0.0449
±10	50 MHz ± 10 kHz	$3.6 \times 10^{-3}$

The magnitude spectrum, for positive frequencies, of a wideband FM signal is,

so power delivered to load

$$P = 2.268 + 2(7.656 + 5.9 + 1.318 + 12.788 + 13.112 + 6.042 + 1.679)$$
  
$$P = 99.258$$
 Watt

#### Case-5

BW = 20.2 kHz

So output of filter will contain

 $f_c$ ;  $f_c \pm f_m$ ;  $f_c \pm 2f_m$ ;  $f_c \pm 3f_m$ ;  $f_c \pm 4f_m$ ;  $f_c \pm 5f_m$ ;  $f_c \pm 6f_m$ ;  $f_c \pm 7f_m$ ;  $f_c \pm 8f_m$ ;  $f_c \pm 9f_m$ ;  $f_c \pm 10f_m$ so power delivered to load

> $P = 2.268 + 2(7.656 + 5.9 + 1.318 + 12.788 + 13.112 + 6.042 + 1.679 + 0.319 + 0.0449 + 3.6 \times 10^{-3})$ P = 99.99 Watt

#### O Comments on the Results:

- The transmission B.W of an FM wave as the separation between the two frequencies beyond which none of the side-frequencies is greater than 1% of the carrier amplitude obtained when the modulation is removed.
- As the value of n<sub>max</sub> increases here the power delivered to the load may also be increased. Because as the modulation index (β) increases, the B.W occupied by the significant side-frequencies drops towards that over which the carrier frequency actually deviates i.e. carrier power decreases and sideband power increases.

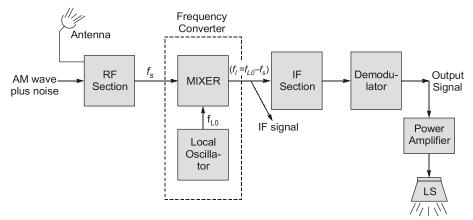

#### **I.7** With the help of a block diagram explain the working of a superheterodyne AM receiver.

[10 marks : 2009]

#### Solution:

A radio receiver is an electronic equipment which picks up the desired signal, rejects the unwanted signal, amplifies the desired signal, demodulates the modulated signal to obtain back the original modulating signal.

⇒ The usual AM radio receiver of superheterodyne (mixing) type is represented schematically in figure below:

(Superheterodyne AM Radio Receiver)

Basically this receiver consists of RF section, a mixer and a local oscillator, an intermediate frequency (IF) section and a demodulator.

#### Working:

- The incoming AM wave is picked up by the receiving antenna and amplified in the RF section which is tuned to the carrier frequency of the incoming wave.
- The combination of mixer and local oscillator (of adjustable frequency) provides a frequency conversion or heterodyning function, where the incoming signal is converted to a predetermined fixed IF (usually lower than the signal frequency). The mixer-local oscillator combination is sometimes referred to as the **First detector**, in this case the Demodulator is called the **Second detector**.

- The IF section consists of one or more stages of tuned amplification. This section provides most of the
  amplification i.e. sensitivity and selectivity (B.W requirements) in the receiver. Because of its narrow
  Bandwidth, the IF amplifier rejects all other frequency except intermediate frequency (IF). Actually, this
  rejection reduces the risk of interference from other stations or sources. Infact, this selection process is
  the key to the superheterodyne receivers exceptional performance.
- The output of the IF section is then applied to the demodulator, the purpose of which is to recover the baseband or modulating signal. If coherent detection is used, then a coherent signal source must be provided in the receiver. The final operation in the receiver is the power amplification so that it make activate the Loudspeaker.
- The Loudspeaker (LS) is a transducer which converts this audio electrical signal into audio sound signal and thus original signal is reproduced i.e., the original transmission is received.
- ⇒ Typical frequency parameters of commercial AM Radio receiver is as follows: RF carrier range = 0.535 – 1.605 MHz Mid-band frequency of IF section = 455 kHz ≈ 0.455 MHz IF Bandwidth = 10 kHz.
- ⇒ The advantages of superheterodyne receiver make it the most suitable for the majority of radio receiver applications like AM, FM, communications, single-sideband, TV and even Radar receiver; all uses superheterodyne principle.
- **1.8** In a FM system, when the audio frequency (AF) is 500 Hz and the AF voltage is 2.4 volt, and frequency deviation is 4.8 kHz if voltage is increased to 7.2 V, what is the new deviation? Now, if the AF voltage is raised to 10 V and AF is dropped to 200 Hz, what is the deviation? Find the modulation index in each case.

Mention two disadvantages of FM over AM.

[10 marks: 2010]

#### Solution:

Audio frequency 
$$f_m = 500 \text{ Hz}$$
  
 $A_m = 2.4 \text{ V}$   
Deviation  $\Delta f = 4.8 \text{ kHz}$   
We know that  
Modulation index  $\beta = \frac{\Delta f}{f_m} = \frac{4.8 \times 10^3}{500}$   
 $\beta = 9.6$   
and Deviation  $\Delta f = k_f A_m$   
 $4.8 \times 10^3 = k_f \times 2.4$   
 $k_f = 2 \times 10^3 \text{ Hz/V}$   
(i) Now  $A_m = 7.2 \text{ V}$   
Deviation  $\Delta f = k_f A_m$  [where  $k_f$  = frequency sensitivity]  
 $\Delta f = 2 \times 10^3 \times 7.2 = 14.4 \text{ kHz}$   
Modulation index,  $\beta = \frac{\Delta f}{f_m} = \frac{14.4 \times 10^3}{500}$   
 $\beta = 28.8$   
(ii)  $A_m = 10 \text{ V}; f_m = 200 \text{ Hz}$   
Deviation  $\Delta f = k_f A_m = 2 \times 10^3 \times 10 = 20 \times 10^3 = 20 \times 10^3 \text{ Hz}}$ 

Modulation index,  $\beta = \frac{\Delta f}{f_m} = \frac{20 \times 10^3}{200} = 100$ 

#### Disadvantage of FM over AM:

- 1. Threshold effect is more pronounced in FM than AM.
- 2. Circuit is more complex.
- 3. FM required more bandwidth than AM because bandwidth for FM is 10 times greater than AM.

#### 1.9 Consider a modulating signal

 $m(t) = 10 \sin(2\pi \times 10^4 t)$ 

that is used to modulate a carrier frequency of 25 MHz.

- (i) Find the bandwidth for 98% power transmission for phase modulation and frequency modulation using  $\beta_p = 10$  and  $\beta_f = 10$ .
- (ii) Repeat (i) when modulating frequency is doubled.
- (iii) Repeat (ii) when amplitude of the modulating signal is halved.

#### Solution:

Given that message signal

	$m(t) = 10\sin(2\pi \times 10^4 t)$	
.:.	$f_m = 10^4 \text{ Hz} = 10 \text{ kHz}$	(i)
Carrier frequency	$f_c = 25 \text{ MHz}$	
(i) Given that	$\beta_{\alpha} = 10,  \beta_{f} = 10$	

i) Given that 
$$\beta_p = 10, \quad \beta_f =$$
  
We know that,  $\beta_p = \frac{K_p A_m}{f_m}$ 

We know that,

Where  $K_p A_m$  maximum phase deviation

$$\begin{split} \beta_p &= \frac{K_p \times 10}{10^4} \\ K_p &= \frac{10 \times 10^4}{10} = 10^4 \text{ rad/V} \\ K_p &\to \text{phase deviation constant} \\ \beta_f &= \frac{K_f A_m}{f_m} \quad K_f \text{- frequency deviation constant} \\ K_f &= 10^4 \text{ Hz/V} \\ &\dots (\text{iii}) \end{split}$$

Effective bandwidth of angle modulated signal which contains atleast 98% of the signal power is given by Carson's rule

 $\mathsf{B.W.} = 2(\beta + 1)f_m$ 

 $\beta_p = \beta_f$ 

... (i) for phase modulated signal

B.W. = 
$$2(\beta_p + 1)f_m$$
  
B.W. =  $2(10 + 1) \times 10^4$ 

B.W. = 220 kHz | for PM.

: B.W. of frequency modulated signal will be same

B.W. of FM modulated signal = 220 kHz | for FM *.*..

[10 marks : 2011]

#### MADE EASY

 $f'_{m} = 2f_{m} = 2 \times 10^{4} \text{ Hz}$ 

(ii) When modulating frequency is doubled

i.e.

... New modulation index for phase modulated and frequency modulated signals.

$$\beta'_{\rho} = \frac{K_{\rho}A_{m}}{f'_{m}} = \frac{10^{4} \times 10}{2 \times 10^{4}} = 5$$
$$\beta'_{f} = \frac{K_{f}A_{m}}{f'_{m}} = \frac{10^{4} \times 10}{2 \times 10^{4}} = 5$$

: B.W. of phase modulated signal

B.W. = 
$$2(\beta'_{p} + 1)f'_{m}$$
  
B.W. =  $2(5 + 1) \times 2 \times 10^{4}$   
B.W. = 240 kHz for PM

 $\beta'_{D} = \beta'_{f}$ 

...

:. B.W. of frequency modulated signal

B.W. = 240 kHz for FM

(iii) Now amplitude of modulating signal is halved.

$$A'_m = Am/2 = 10/2 = 5$$

:. New modulation index of phase and frequency modulated signals.

$$\beta_p'' = \frac{K_p A_m'}{f_m'} = \frac{10^4 \times 5}{2 \times 10^4} = 2.5 = 2.5$$

: New bandwidth of phase and frequency modulated signals

B.W. = 
$$2(\beta''_{p} + 1)f'_{m}$$
  
B.W. =  $2(2.5 + 1) \times 2 \times 10^{4}$ 

B.W. = 140 kHz for PM

...

 $\beta_p'' = \beta_f''$ 

 $\Rightarrow$  B.W. for both signals will be same.

: B.W. of frequency modulated signal will be

B.W. = 140 kHz for FM

**1.10** In an AM Transmitter, antenna current is 8 amperes, when only the carrier is sent but is increased to 8.93 amperes when carrier is modulated by a single sine wave. Determine the percentage of Modulation. Also evaluate the antenna current when the percentage of Modulation is changed to 80%.

[10 marks : 2012]

#### Solution:

We know that, for single sine wave modulation

$$P_t = P_c \left( 1 + \frac{m^2}{2} \right) \tag{i}$$

where,

 $P_t$  = Total transmitted power  $P_c$  = Carrier power

m = Modulation index $P_t = I_t^2 R$  $P_c = I_c^2 R$ Substitute the values of  $P_t$  and  $P_c$  in equation (i)  $I_t^2 R = I_c^2 R \left( 1 + \frac{m^2}{2} \right)$  $I_t^2 = I_c^2 \left(1 + \frac{m^2}{2}\right)$  $I_t = I_c \sqrt{1 + \frac{m^2}{2}}$  $I_t = 8.93 \text{ Amp.}$ Given that  $I_c = 8 \text{ Amp}$ m = ? $8.93 = 8\sqrt{1 + \frac{m^2}{2}}$ So.  $\sqrt{1+\frac{m^2}{2}} = \frac{8.93}{8} = 1.116$  $1 + \frac{m^2}{2} = 1.246$  $\frac{m^2}{2} = 0.246$  $m^2 = 0.492$ *m* = 0.7014 **Ans.**  $\% m = 0.7014 \times 100 = 70.14\%$  Ans.  $I_c = 8 \text{ Amp}$ Given that  $m = 80\% = \frac{80}{100} = 0.8$  $I_t = ?$  $I_t = I_c \sqrt{1 + \frac{m^2}{2}} = 8\sqrt{1 + \frac{(0.8)^2}{2}} = 8\sqrt{1 + 0.32} = 8\sqrt{1.32}$ We know that,  $I_t = 9.1913 \,\mathrm{Amp}$ 

1.11 Find the carrier and modulating frequencies, the modulation index and the maximum deviation of the FM wave represented by the voltage equation

 $v = 12 \sin (6 \times 10^8 t + 5 \sin 1250 t)$ 

What power will this FM wave dissipate in a 10  $\Omega$  resistor?

#### [5 marks : 2014]

#### Solution:

 $v(t) = 12\sin(6 \times 10^8 t + 5\sin 1250 t)$ 

Single-tone F.M. modulated wave equation can be given by,

$$V(t) = A \sin \left[ \omega_c t + k_f \int V_m \cos(\omega_m t) dt \right] \qquad \dots(i)$$

Where,  $\omega_c$  is carrier frequency and  $V_m \cos \omega_m t$  is modulating signal. For single tone modulation the above equation reduces to

$$V_{in} = A \sin[\omega_c t + \beta \sin(\omega_m t)] \qquad ...(ii)$$
  
$$\beta = \text{modulation index} = \frac{\Delta f}{f_m}$$

where,

Thus, comparing the equation (ii) with the given equation, we get,

$$\omega_c = 2\pi f_c = 6 \times 10^8$$

*.*:.

$$f_{c} = \frac{6 \times 10^{8}}{2\pi} = 95.49 \text{ MHz}$$
$$f_{m} = \frac{1250}{2\pi} = 198.94 \text{ Hz}$$
$$\beta = 5$$

$$\beta = 1$$

Now, the frequency deviation can be given as

$$\Delta f = f_m \cdot \beta = 5 \times 198.94 = 995 \,\text{Hz}$$

Power dissipated in 10 W resistor

$$P = \frac{V_m^2}{2R} = \frac{12^2}{2 \times 10} = 7.2 \,\mathrm{W}$$

- 1.12 (i) The antenna current of an AM broadcast transmitter, modulated to a depth of 40 percent by an audio sine wave, is 11 amperes. It increases to 12 amperes as a result of simultaneous modulation by another audio sine wave. What is the modulation index due to this second wave?
  - (ii) A certain transmitter radiates 9 kW with the carrier unmodulated and 10.125 kW when the carrier is simultaneously modulated. Estimate the modulation index. If another sine wave, corresponding to 40% modulation, is transmitted simultaneously, find out the total radiated power.

[5 + 5 marks : 2015]

#### Solution:

(i) Given that, depth of modulation, Antenna current,

$$\mu_{1} = 40\% = 0.4$$

$$I_{t} = 11 \text{ A}$$

$$I_{t}^{2} = I_{c}^{2} \left(1 + \frac{\mu_{1}^{2}}{2}\right)$$

$$I_{c} = I_{t} \sqrt{\frac{1}{1 + \frac{\mu_{1}^{2}}{2}}} = 11 \sqrt{\frac{1}{1 + \frac{(0.4)^{2}}{2}}} = 10.58 \text{ A}$$

Now, given that

antenna current  $I_t = 12 \text{ A}$ Let the second modulated wave be of modulation index  $\mu_2$ 

$$I_t^2 = I_c^2 \left( 1 + \frac{\mu_1^2}{2} + \frac{\mu_2^2}{2} \right)$$
  
(12)<sup>2</sup> = (10.58)<sup>2</sup>  $\left( 1 + \frac{(0.4)^2}{2} + \frac{\mu_2^2}{2} \right)$   
 $\mu_2 = 0.64$ 

From here,

 $P_{c} = 9 \text{ kW}$  $P_{t} = 10.125 \text{ kW}$ 

 (ii) Given that, Carrier power, Total power, Let modulation depth is μ<sub>1</sub>

$$P_{t} = P_{c} \left( 1 + \frac{\mu_{1}^{2}}{2} \right)$$
  
10.125 = 9  $\left( 1 + \frac{\mu_{1}^{2}}{2} \right)$   
 $\mu_{1} = \frac{1}{2} \text{ or } 50\%$ 

From here

Simultaneous modulated with 
$$\mu_2 = 40\%$$

$$P_t = P_c \left( 1 + \frac{\mu_1^2}{2} + \frac{\mu_2^2}{2} \right) = 9 \left( 1 + \frac{(0.5)^2}{2} + \frac{(0.4)^2}{2} \right) \text{kW} = 10.845 \text{ kW}$$

1.13 Explain and differentiate between baseland communication and carrier communication. An audio FM system with audio frequency of 1 kHz and audio frequency voltage of 4.8 V is used with frequency deviation of 7.2 kHz. Calculate modulation index. If the voltage of audio signal now increased to 8.2 V, what is new deviation? Now if both audio voltage and frequency are changed to 10 V and 200 Hz calculate deviation and modulation Index.

[10 marks : 2017]

#### Solution:

**Baseband Communication:** In a baseband communication system, the source information (baseband signal) will be transmitted to the destination in it's original frequency range. No modulation is used in this communication technique.

**Carrier Communication:** In a carrier communication system, the source information is modulated on to a high frequency carrier signal and the modulated signal will be transmitted to the destination.

S. No.	Baseband Communication	Carrier Communication	
1.	No modulation is used.	Modulation is used.	
2.	Signal should be transmitted through a private physical medium (co-axial cables, twisted pair cable, waveguides etc.)	Signal can be transmitted through both physical mediums and free space.	
3.	Frequency division multiplexing is not possible	Frequency division multiplexing is possible.	
4.	Time division multiplexing is possible	Time division multiplexing is possible	
5.	Example: Public addressing system	Example FM and AM broadcasting	

#### Given data:

Audio frequency,
$$f_m = 1 \text{ kHz}$$
Audio frequency voltage, $A_m = 4.8 \text{ V}$ For the initial state of the ini

Frequency deviation,  $\Delta f = 7.2 \text{ kHz}$ 

The modulation index  $\beta$  of the FM signal with above parameters can be given as,

$$\beta = \frac{\Delta f}{f_m} = \frac{7.2}{1} = 7.2$$

#### When voltage $(A_m)$ is increased to 8.2 V :

The frequency deviation  $(\Delta f_1)$  for the modified voltage  $(A_m)$  can be given as,

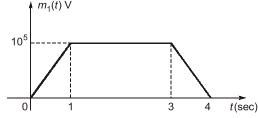

$$\Delta f_1 = K_f A_{m1} = \frac{\Delta f}{A_m} \times A_{m1} = \frac{7.2 \text{ kHz}}{4.8 \text{ V}} \times 8.2 \text{ V} = 12.3 \text{ kHz}$$

When both audio voltage and frequency are changed to 10 V and 200 Hz respectively :

The frequency deviation ( $\Delta f_2$ ) for the modified voltage ( $A_{m2}$ ) and frequency ( $f_{m2}$ ) can be given as,

$$\Delta f_2 = \frac{\Delta f}{A_m} \times A_{m2} = \frac{7.2 \text{ kHz}}{4.8 \text{ V}} \times 10 \text{ V} = 15 \text{ kHz}$$
$$\beta_2 = \frac{\Delta f_2}{f_{m2}} = \frac{15 \text{ kHz}}{200 \text{ Hz}} = \frac{15000}{200} = 75$$

**1.14** Consider a message signal  $m_1(t)$  as shown and message signal  $m_2(t) = \text{sinc}(2 \times 10^4 t)$ , in volts.

- (i) If  $m_1(t)$  is frequency modulated on a carrier with frequency  $10^6$  Hz with a frequency deviation constant ( $k_f$ ) equal to 5 Hz/V, what is the maximum instantaneous frequency of the modulated signal?
- (ii) If  $m_1(t)$  is phase modulated with phase deviation constant  $(k_p)$  equal to 3 rad/V, what is the maximum instantaneous frequency of the modulated signal? What is the minimum instantaneous frequency of the modulated signal?
- (iii) If  $m_2(t)$  is frequency modulated with  $k_f = 10^3$  Hz/V, what is the maximum instantaneous frequency of the modulated signal? What is the bandwidth of the modulated signal?

#### [10 marks : 2018]

#### Solution:

(i) Carrier frequency,  $f_c = 10^6 \text{Hz}$ Frequency deviation constant,

> $k_f = 5 \text{ Hz/V}$ For frequency modulated signal, the instantaneous frequency (*f*,) is given as

$$f_i = f_c + k_f m_1(t)$$

 $f_i$  will be maximum when  $m_1(t)$  is maximum

$$m_1(t)\Big|_{\rm max} = 10^5 \,\rm V$$

Therefore,

$$f_{imax} = f_c + k_f m(t) |_{max} = 10^6 + 5 \times 10^5 = 1.5 \text{ MHz}$$

(ii) When  $m_1(t)$  is phase-modulated with phase deviation constant  $(k_p)$ , the instantaneous phase of the modulated signal is given as

$$\theta_i = 2\pi f_c t + k_p m_1(t)$$

Hence, instantaneous frequency can be written as

$$f_{i} = \frac{1}{2\pi} \cdot \frac{d\theta_{i}}{dt} = \frac{1}{2\pi} \frac{d}{dt} (2\pi f_{c}t + k_{p}m_{1}(t)) = f_{c} + \frac{k_{p}}{2\pi} \cdot \frac{d}{dt}m_{1}(t)$$
  
Maximum instantaneous frequency,  
$$f_{c} = \frac{k_{p}}{2\pi} \frac{d}{dt}m_{1}(t)$$

$$f_{i\max} = f_c + \frac{k_P}{2\pi} \frac{d}{dt} m_1(t) \Big|_{\max} = 10^6 + \frac{3}{2\pi} \times 10^5 = 1.048 \text{ MHz}$$

Minimum instantaneous frequency,

$$f_{i\min} = f_c + \frac{k_p}{2\pi} \frac{d}{dt} m_1(t) \Big|_{\min} = 10^6 + \frac{3}{2\pi} \times (-10^5) = 0.952 \text{ MHz}$$
