19. Reciprocating Pump .....	214

## Fluid Properties

**Q1** The space between two square flat parallel plates is filled with oil. Each side of the plate is 60 cm. The thickness of the oil film is 12.5 mm. The upper plate, which moves at 2.5 metre per sec requires a forces of 98.1 N to maintain the speed. Determine:

- the dynamic viscosity of the oil in poise, and
- the kinematic viscosity of the oil in stoke if the specific gravity of the oil is 0.95.

**Solution:**

**Given:** Each side of a square plate = 60 cm = 0.60 m

∴ Area,  $A = 0.6 \times 0.6 = 0.36 \text{ m}^2$

Thickness of oil film,  $dy = 12.5 \text{ mm} = 12.5 \times 10^{-3} \text{ m}$

Velocity of upper plate,  $u = 2.5 \text{ m/sec}$

∴ Change of velocity between plates,

$$du = 2.5 \text{ m/sec}$$

Force required on upper plate,  $F = 98.1 \text{ N}$

∴ Shear stress,

$$\tau = \frac{\text{Force}}{\text{Area}} = \frac{F}{A}$$

$$= \frac{98.1 \text{ N}}{0.36 \text{ m}^2} = 27.25 \text{ N/m}^2$$

(i) Let  $\mu$  = Dynamic viscosity of oil

$$\tau = \mu \frac{du}{dy}$$

or  $27.25 = \mu \times \frac{2.5}{12.5 \times 10^{-3}}$

$$\therefore \mu = 27.25 \times \frac{12.5 \times 10^{-3}}{2.5} = 1.3635 \text{ Ns/m}^2 \quad (\because 1 \text{ Ns/m}^2 = 10 \text{ poise})$$

$$= 1.3635 \times 10 = 13.635 \text{ Poise}$$

(ii) Specific gravity of oil,

$$S = 0.95$$

Let

$\nu$  = kinematic viscosity of oil

Mass density of oil,

$$\rho = S \times 1000 = 0.95 \times 1000 = 950 \text{ kg/m}^3$$

Using the relation,

$$\nu = \frac{\mu}{\rho}$$

We get,

$$\begin{aligned} \nu &= \frac{1.3635 \text{ Ns/m}^2}{950 \text{ kg/m}^3} = 0.001435 \text{ m}^2/\text{sec} \\ &= 0.001435 \times 10^4 \text{ cm}^2/\text{s} \\ &= 14.35 \text{ stokes} \end{aligned}$$

- Q2** Calculate the dynamic viscosity of an oil, which is used for lubrication between a square plate of size  $0.8 \text{ m} \times 0.8 \text{ m}$  and an inclined plane with angle of inclination  $30^\circ$  as shown in figure. The weight of the square plate is  $300 \text{ N}$  and it slides down the inclined plane with a uniform velocity of  $0.3 \text{ m/s}$ . The thickness of oil film is  $1.5 \text{ mm}$ .

**Solution:**

**Given:** Area of plate,  $A = 0.8 \times 0.8 = 0.64 \text{ m}^2$   
 Angle of plane,  $\theta = 30^\circ$   
 Weight of plate,  $W = 300 \text{ N}$   
 Velocity of plate,  $u = 0.3 \text{ m/s}$   
 Thickness of oil film,  $t = dy = 1.5 \text{ mm} = 1.5 \times 10^{-3} \text{ m}$

Let the viscosity of fluid between plate and inclined plane is  $\mu$ .

Component of weight  $W$ , along the plane  $= W \cos 60^\circ = 300 \cos 60^\circ = 150 \text{ N}$

Thus the shear force,  $F$ , on the bottom surface of the plate  $= 150 \text{ N}$

and shear stress, 
$$\tau = \frac{F}{\text{Area}} = \frac{150}{0.64} \text{ N/m}^2$$

Now, 
$$\tau = \mu \frac{du}{dy}$$

$$du = \text{change of velocity} = u - 0 = 0.3 \text{ m/sec}$$

$$dy = t = 1.5 \times 10^{-3} \text{ m}$$

$$\therefore \frac{150}{0.64} = \mu \times \frac{0.3}{1.5 \times 10^{-3}}$$

$$\mu = \frac{150 \times 1.5 \times 10^{-3}}{0.64 \times 0.3} = 1.17 \text{ Ns/m}^2 = 11.7 \text{ Poise}$$

- Q3** The dynamic viscosity of an oil, used for lubrication between a shaft and sleeve is  $6 \text{ poise}$ . The shaft is of diameter  $0.4 \text{ m}$  and rotates at  $190 \text{ rpm}$ . Calculate the power lost in the bearing for a sleeve length of  $90 \text{ mm}$ . The thickness of the oil film is  $1.5 \text{ mm}$ .

**Solution:**

**Given:**

Viscosity, 
$$\mu = 6 \text{ Poise}$$
  

$$= \frac{6}{10} \frac{\text{Ns}}{\text{m}^2} = 0.6 \text{ Ns/m}^2$$

Dia. of shaft,  $D = 0.4 \text{ m}$

Speed of shaft,  $N = 1900 \text{ rpm}$

Sleeve length,  
Thickness of oil film,

$$L = 90 \text{ mm} = 90 \times 10^{-3} \text{ m}$$

$$t = 1.5 \text{ mm} = 1.5 \times 10^{-3} \text{ m}$$

Tangential velocity of shaft,

$$u = \frac{\pi DN}{60}$$

$$= \frac{\pi \times 0.4 \times 190}{60} = 3.98 \text{ m/s}$$

Using the relation,

$$\tau = \mu \frac{du}{dy}$$

where,  $du$  = Change of velocity =  $u - 0 = u = 3.98 \text{ m/s}$   
 $dy$  = Change of distance =  $t = 1.5 \times 10^{-3} \text{ m}$

$$\tau = 10 \times \frac{3.98}{15 \times 10^{-3}} = 1592 \text{ N/m}^2$$

This is shear stress on shaft,

$\therefore$  Shear force on the shaft,

$$F = \text{Shear stress} \times \text{Area}$$

$$= 1592 \times \pi D \times L = 1592 \times \pi \times 0.4 \times 90 \times 10^{-3} = 180.05 \text{ N}$$

Torque on the shaft,

$$T = \text{Force} \times \frac{D}{2}$$

$$= 180.5 \times \frac{0.4}{2} = 36.01 \text{ Nm}$$

$\therefore$

$$\text{Power lost} = \frac{2\pi NT}{60}$$

$$= \frac{2\pi \times 190 \times 36.01}{60} = 716.48 \text{ W}$$

**Q4** A vertical gap 23.5 mm wide of infinite extent contains oil of specific gravity 0.9 and viscosity 2.5 N-s/m<sup>2</sup>. A metal plate 1.5 m × 1.5 m × 1.5 mm weighing 50 N is to be lifted through the gap at a constant speed of 0.1 m/sec. Estimate the force required to lift the plate.

**Solution:**

**Given:**

Width of gap = 23.5 mm

Viscosity,  $\mu$  = 2.5 Ns/m<sup>2</sup>

Specific gravity oil = 0.9

$\therefore$  Weight density of oil =  $0.9 \times 1000 = 900 \text{ kgf/m}^3$   
 $= 900 \times 9.81 \text{ N/m}^3$

( $\because 1 \text{ kgf} = 9.81 \text{ N}$ )

Assuming that the plate lies in the middle of the gap

Volume of plate =  $1.5 \text{ m} \times 1.5 \text{ m} \times 1.5 \text{ mm}$   
 $= 1.5 \times 1.5 \times 0.0015 \text{ m}^3$   
 $= 0.003375 \text{ m}^3$

Thickness of plate = 1.5 mm

Velocity of plate = 0.1 m/sec

Weight of plate = 50 N

When the plate is in the middle of the gap, the distance of plate from

$$\text{Vertical surface of the gap} = \left( \frac{\text{Width of gap} - \text{Thickness of plate}}{2} \right)$$

$$= \left( \frac{23.5 - 1.5}{2} \right) = 11 \text{ mm} = 0.011 \text{ m}$$

Now, shear force on left side of the metallic plate

$$F_1 = \text{Shear stress} \times \text{Area}$$

$$= \mu \left( \frac{du}{dy} \right)_1 \times (1.5 \times 1.5) = 2.5 \times \left( \frac{0.1}{0.011} \right) \times 1.5 \times 1.5 = 51.136 \text{ N}$$

Similarly, the shear force on the right side of the metallic plate

$$F_2 = \text{Shear stress} \times \text{Area}$$

$$= 2.5 \times \left( \frac{0.1}{0.011} \right) \times (1.5 \times 1.5) = 51.136 \text{ N}$$

$$\therefore \text{Total shear force} = F_1 + F_2 = 51.136 + 51.136 = 102.272 \text{ N}$$

In this case the weight of plate (which is acting downward) and upward thrust is also to be taken into account.

$$\begin{aligned} \therefore \text{The upward thrust} &= \text{weight of fluid displaced} = \rho vg \\ &= (\text{unit weight of fluid}) \times \text{Volume of fluid displaced} \\ &= 9.81 \times 900 \times 0.003375 \\ &= 29.80 \text{ N} \end{aligned}$$

$$\begin{aligned} \text{The net force acting in the downward direction due to the weight of the plate and upward thrust} \\ &= \text{weight of plate} - \text{upward thrust} = 50 - 29.80 = 20.20 \text{ N} \end{aligned}$$

$$\begin{aligned} \therefore \text{Total force required to lift the plate up} \\ &= \text{Total shear force} + 20.20 = 102.272 + 20.20 = 122.472 \text{ N} \end{aligned}$$

**Q5** The pressure outside the droplet of water of diameter 0.04 mm is 10.32 N/cm<sup>2</sup> (atmospheric pressure). Calculate the pressure within the droplet if surface tension is given as 0.0725 N/m of water.

**Solution:**

$$\begin{aligned} \text{Given, dia. of droplet, } d &= 0.04 \text{ mm} = 0.04 \times 10^{-3} \text{ m} \\ \text{Pressure outside the droplet} &= 10.32 \text{ N/cm}^2 = 10.32 \times 10^4 \text{ N/m}^2 \\ \text{Surface tension, } \sigma &= 0.0725 \text{ N/m} \end{aligned}$$

The **pressure inside the droplet**, in excess of outside pressure is given by

$$p = \frac{4\sigma}{d}$$

$$\begin{aligned} &= \frac{4 \times 0.0725}{0.04 \times 10^{-3}} = 7250 \text{ N/m}^2 \\ &= \frac{7250 \text{ N}}{10^4 \text{ cm}^2} = 0.725 \text{ N/cm}^2 \end{aligned}$$

$$\begin{aligned} \text{Pressure inside the droplet} &= p + \text{pressure outside the droplet} \\ &= 0.725 + 10.32 = 11.045 \text{ N/cm}^2 \end{aligned}$$

- Q6** Calculate the capillary effect in mm in a glass tube 3 mm in diameter when immersed in (a) water (b) mercury. Both the liquids are at 20°C and the values of the surface tensions for water and mercury at 20°C in contact with air are respectively 0.0736 N/m and 0.51 N/m. Contact angle for water = 0° and for mercury = 130°.

**Solution:**

The capillary rise (or depression) is given as

$$h = \frac{2\sigma \cos \theta}{\rho g r}$$

(a) For water  $\theta = 0^\circ$ ,

$$\cos \theta = 1$$

$$\sigma = 0.0736 \text{ N/m}$$

$$\rho g = 9810 \text{ N/m}^3$$

$$d = 3 \text{ mm}$$

$$r = \frac{3}{2} = 1.5 \text{ mm} = 1.5 \times 10^{-3} \text{ m}$$

By substitution, we get

$$h = \frac{2 \times 0.0736 \times 1}{9810 \times 1.5 \times 10^{-3}} \\ = 1.00 \times 10^{-2} \text{ m} = 10 \text{ mm}$$

(b) For mercury  $\theta = 130^\circ$ ,

$$\cos \theta = -0.6428$$

$$\sigma = 0.51 \text{ N/m}$$

$$\rho g = (13.6 \times 9810) \text{ N/m}^3$$

$$r = \frac{3}{2} = 1.5 \text{ mm} = 1.5 \times 10^{-3} \text{ m}$$

By substitution, we get

$$h = \frac{2 \times 0.51 \times (-0.6425)}{13.6 \times 9810 \times 1.5 \times 10^{-3}} \\ = -3.276 \times 10^{-3} \text{ m} \\ = -3.276 \text{ mm}$$

The negative (–) sign in the case of mercury indicates that there is capillary depression.

- Q7** For capillarity rise between two thin vertical plates spaced 't' distance apart. Calculate the distance between the plates when the capillarity rise is not to exceed 60 mm. Assume surface tension of water at 20°C as 0.075 N/meter.

**Solution:**

For two vertical plates, 't' distance apart

Let width of plate be 'b' and contact angle be 'θ'

Force due to surface tension = Force due to gravity

$$2\sigma \cos \theta b = \rho g (b \times t)h$$

Height of capillarity rise,

$$h = \frac{2\sigma \cos \theta}{\rho g t}$$

For  $\sigma = 0.075 \text{ N/m}$  and  $h = 60 \text{ mm}$

Assuming  $\theta = 0^\circ$  i.e.,  $\cos \theta = 1$

$$0.06 = \frac{2 \times 0.075 \times 1000}{9.81 \times 1000 \times t} \\ t = 0.255 \text{ mm}$$

**Q8** The density of sea water at free surface where pressure is 98 kPa is 1030 kg/m<sup>3</sup>. Taking bulk modulus of sea water to be  $2.34 \times 10^9$  N/m<sup>2</sup> (assume constant), determine the density and pressure at a depth of 2500 m. Neglect the effect of temperature

**Solution:**

Calculation of density:

$$K = 2.34 \times 10^9 \text{ N/m}^2$$

$$K = \rho \frac{dP}{d\rho}$$

Since

$$dP = \gamma dh$$

$\Rightarrow$

$$K = \frac{\rho \gamma dh}{d\rho} = \rho^2 g \frac{dh}{d\rho}$$

$$\int_{\rho_A}^{\rho_B} \frac{d\rho}{\rho^2} = \int_0^{H=2500 \text{ m}} \frac{g}{K} dh$$

$\Rightarrow$

$$\frac{1}{\rho(-1)} \Big|_{\rho_A}^{\rho_B} = \frac{g}{K} \times 2500$$

$\Rightarrow$

$$\frac{1}{\rho_A} - \frac{gH}{K} = \frac{1}{\rho_B}$$

$\therefore$

$$\rho_B = \frac{1}{\left( \frac{1}{\rho_A} - \frac{gH}{K} \right)}$$

$$\rho_B = \frac{1}{\frac{1}{1030} - \frac{9.81 \times 2500}{2.34 \times 10^9}} = 1041.24 \text{ kg/m}^3$$

Calculation of pressure:

$$K = \frac{dP}{\left( \frac{d\rho}{\rho} \right)}$$

$$\int_{P_A}^{P_B} dP = K \int_{\rho_A}^{\rho_B} \frac{d\rho}{\rho}$$

$$P_B - P_A = K [\ln \rho]_{\rho_A}^{\rho_B}$$

$$P_B = P_A + K \ln \left( \frac{\rho_B}{\rho_A} \right)$$

$$\begin{aligned} P_B &= 98 + 2.34 \times 10^6 \ln \left( \frac{1041.24}{1030} \right) \\ &= 25495.20 \text{ kPa} = 25.5 \text{ MPa} \end{aligned}$$

**Q9** Consider a fluid of viscosity  $\mu$  between two circular parallel plates of radii 'R' separated by a distance 'h'. Upper plate is rotated at an angular velocity  $\omega$  whereas bottom plate is held stationary. The velocity profile between two plate is linear. Estimate the torque experienced by the bottom plate.

**Solution:**

Consider an annual ring with width  $dr$  at radius ' $r$ '

Stress stress on the ring,  $\tau = \mu \left( \frac{du}{dy} \right) = \mu \frac{\omega r}{h} \quad \dots(i)$

Force on the ring,  $F = \tau \times \text{area of contact}$

$$= \left( \frac{\mu \omega r}{h} \right) (2\pi r dr)$$

$\therefore$  Torque on the ring,  $dT = F.r = \left( \frac{2\pi\mu\omega}{h} \right) r^2 . dr . r$

$$= \left( \frac{2\pi\mu\omega}{h} \right) r^3 . dr$$

$\therefore$  Total torque on the disc,  $T = \int_0^R \left( \frac{2\pi\mu\omega}{h} \right) r^3 dr$

$$= \left( \frac{2\pi\mu\omega}{h} \right) \left( \frac{R^4}{4} \right)$$

$$\boxed{T = \frac{\pi\mu\omega R^4}{2h}}$$

**Q.10** A three-cylinder car has pistons of 75 mm and cylinders of 75.1 mm. Find the percentage change in force required to drive the piston, when the lubricant warms from 25°C to 100°C. The dynamic viscosity of the lubricant at 25°C is 2 Ns/m<sup>2</sup> and at 100°C, it is 0.4 Ns/m<sup>2</sup>.

Solution:

Given,  $d_1$ , Piston diameter = 75 mm  
 $d_2$ , Cylinder diameter = 75.1 mm

$$\therefore \text{Clearance} = \frac{d_1 - d_2}{2} = \frac{0.1}{2} = 0.05 \text{ mm}$$

Also,  $\mu_{25} = 2 \text{ Ns/m}^2$ ,  $\mu_{100} = 0.4 \text{ Ns/m}^2$   
As per **Newtonian's law of viscosity**,

$$\tau = \mu \frac{du}{dy}$$

Force required to drive the piston  $F = \tau A_s$

$$\therefore F = \left( \mu \frac{du}{dy} \right) A_s$$

$$\therefore \frac{F_1}{F_2} = \frac{\mu_1}{\mu_2} \quad (\text{The other factors remains constant})$$

$$\Rightarrow \frac{F_{25^\circ}}{F_{100^\circ}} = \frac{\mu_{25^\circ}}{\mu_{100^\circ}} = \frac{2.0}{0.4} = 5.0$$

$$\% \text{ change in force, } \Delta F = \left( \frac{F_{25} - F_{100}}{F_{25}} \right) \times 100 = 1 - \frac{1}{5} = 80\%$$

$\Rightarrow$  80% force reduces to drive the same piston.

**Q.11** Two coaxial cylinders 250 mm high have a liquid in between them, the outer cylinder has internal diameter 100 mm and the internal cylinder has external diameter 97.5 mm. Find the viscosity of liquid which produces a torque of 1 Nm upon the inner cylinder when outer one rotates at 90 rpm.

**Solution:**

For given assembly

Internal diameter,  $d_i = 97.5 \text{ mm}$

External diameter,  $d_o = 100 \text{ mm}$

Speed of external cylinder,  $N = 90 \text{ rpm}$

Height of cylinder,  $H = 250 \text{ mm}$

**Tangential velocity** of external cylinder,

$$u = \frac{\pi d_o N}{60}$$

$$= \frac{\pi \times 0.1 \times 90}{60} = 0.47 \text{ m/s}$$

Shear stress at internal cylinder,  $\tau = \mu \frac{\partial V}{\partial y}$

$$= \frac{\mu \times 0.47}{\frac{0.1 - 0.0975}{2}} = 376 \mu$$

Force on internal cylinder,  $F = \tau A$

$$= 376 \mu \times \pi \times 0.0975 \times 0.25 = 28.79 \mu$$

Torque on internal cylinder,  $T = F \frac{d_i}{2}$

$$1 = \frac{28.79 \mu \times 0.0975}{2}$$

$$\mu = 0.712 \text{ Pa-s}$$
